

Mathéo Diep

Quantitative Developer — Institutional Expert Advisors (MQL5)

I design, validate, and deploy automated trading systems built on Smart Money Concepts (ICT) and institutional risk management — every edge proven on data before a single line of code ships.

SMART MONEY CONCEPTS / ICT

MQL5 DEVELOPMENT

QUANTITATIVE RESEARCH

RISK MANAGEMENT

WALK-FORWARD VALIDATION

A selection of **production-grade Expert Advisors** I've built for MetaTrader 5 — from data-validated breakout systems to full ICT execution engines across gold and US indices. Each is engineered to an institutional standard: objective rules, controlled risk, and verifiable behavior.

FLAGSHIP SYSTEM

XAUUSD Breakout EA — a validated edge

XAUUSD Breakout EA

LIVE FORWARD TESTING

Volatility-breakout system on gold, derived from historical confluence analysis and confirmed by walk-forward validation.

POSITIVE WF WINDOWS

~27 mo

VALIDATION PERIOD

Rather than starting from a hunch, this system was reverse-engineered from the market itself: I analyzed the statistical conditions present during gold's largest historical moves, isolated the highest-signal confluences, then validated the resulting edge across **three independent walk-forward windows** — all positive, with win rates of 56–69%. The configuration is now in live forward testing on a demo account under strict, pre-committed risk rules.

- Confluence entry model** — volume Z-score spikes filtered against proximity to key liquidity levels
- Trend-aligned execution** — EMA structure confirms directional bias before any entry
- Volatility-adaptive risk** — ATR-based stops with a 2.5:1 reward-to-risk target
- 24/5 multi-session coverage** — London, New York, and Asia killzones
- Percent-of-equity sizing** — prop-firm compliant position management
- Full signal traceability** — every decision logged with its exact rationale

ENGINEERING CAPABILITY

Institutional Systems Built

SMC / ICT Execution Engine

XAUUSD · MULTI-TIMEFRAME

A complete ICT trade-execution system implementing the full institutional sequence, end to end, with multi-target trade management.

- Full ICT sequence** — liquidity sweep → CHoCH → Order Block → limit entry
- Multi-timeframe logic** — H4/H1 bias driving M15 execution
- Multi-target management** — partial take-profit, break-even, structural trailing
- Daily risk governance** — loss limits and session killzones
- ~1,200 lines** — fully compiled, lifecycle-reviewed

Multi-Index PDA Engine

US500 · USTEC · US30

A multi-symbol institutional-level detection engine that maps ICT price-delivery arrays across three indices to derive inter-market bias.

- Simultaneous coverage** — US500, USTEC and US30 in one engine
- Five PDA types** — Order Blocks, Rejection Blocks, FVG / iFVG, liquidity swings
- Dual-timeframe analysis** — D1 + H4 feeding an inter-market bias
- Modular architecture** — bloc-by-bloc, each component validated in isolation
- Session-sweep entries** — M1 liquidity-sweep + iFVG model

HOW I WORK

An institutional process, not guesswork

Evidence before code. Every time.

The discipline that separates a system that works from one that looks good in a single backtest.

Statistical validation first

Every edge is proven in Python on historical data before a single line of MQL5 is written.

Walk-forward, not in-sample

Edges are confirmed across multiple out-of-sample windows before any forward deployment.

One variable per test

Changes are isolated and measured independently — no curve-fitting, no compounded assumptions.

Risk-first deployment

Pre-committed drawdown and loss-limit rules govern every system from day one.

Let's build something that holds up out of sample.

Available for custom EA development, strategy automation, and quantitative validation on MetaTrader 5.
